

ABSTRACT OF DISCLOSURE

The system of the present invention gives a load to a computer system according to load parameter specification from a system administrator, measures a response and a throughput while giving the load to the computer system, then measures a resource situation of each resource while the load is given. Then, it determines load monitoring conditions relating to a monitoring point, a monitoring item and a threshold from results of measuring the response and throughput and the results of measuring the resource situation and performs load monitoring on the determined load monitoring conditions.
